Abstract

Educational designers often develop a ‘powerful learning environment’ that is subsequently implemented by teachers. Due to a lack of cooperation with teachers they may receive limited feedback on the quality of their design and the way it is implemented. This study focuses on teachers’ perceptions of a Dutch innovative learning environment called the “Second Phase”, as well as their desires and their dis/satisfaction with this environment. The results show that teachers are reserved about student autonomy and productive learning. Perceptions and desires are related to their individual approaches to teaching. The findings provide useful feedback for designers and a starting point to intensify their cooperation with teachers.

Keywords: Educational innovation; Secondary education; Teacher conception; Teacher perception; Cooperation between designers and teachers

During the last decade, many initiatives to modernise education and to optimise student learning have been taken place in Dutch schools. Principles of cognitive psychology and constructivism are the basis for such innovations, which should eventually lead to “powerful learning environments”. Such learning environments are aimed to reach the main goals of modern education: acquisition of high-quality knowledge, problem-solving skills, self-directed learning skills, and transferability of knowledge and skills. In the literature, several characteristics of a design of a powerful learning environment are described, like active knowledge construction, gradual transfer of responsibility, and complex and realistic learning tasks (see Könings, Brand-Gruwel, & van Merriënboer, 2005, for an overview).

It is a general risk of large-scale innovations that educational designers develop a design or blueprint for a powerful learning environment that teachers subsequently do not or cannot fully implement in their teaching. This seems to have happened also in the innovation of Dutch secondary education (Veugelers, de Jong, & Schellings, 2004). A nationwide innovation in the higher grades of Dutch secondary education started in 1998, aiming to develop a powerful learning environment that should predominantly promote students’ acquisition of self-directed learning skills. Teachers play a crucial role in the interpretation of an innovative
design and its translation to educational practice. Therefore, the main goal of the current study is to find out how teachers think about the new powerful learning environment and which factors influence their perspective. Related aims are to investigate whether teachers in Dutch secondary education perceive the current learning environment as a powerful one, what they desire in this learning environment, and with which elements of the perceived learning environment they are dis/satisfied.

Investigating teachers’ perceptions of the learning environment gives insight in the extent to which the educational design has been successfully implemented. First of all, teachers are able to give information about successfully or unsuccessfully implemented aspects of the original design in the factual learning environment, for example, the degree to which productive learning and self-directed learning take place. This provides information about the current state of the implementation and its agreement with the original design. Secondly, teachers are an important source of feedback for educational designers, because not implementing particular aspects of the original design could also mean that it is not workable or feasible in practice. The design may not contain sufficient guidelines for good implementation or may simply not be suitable for realisation in educational practice.

When trying to implement a new educational design, teachers may experience failing preconditions at four levels: (1) the educational design itself, (2) the school, (3) the students, and (4) their own competencies. First, designers do not always take co-accountability for the translation of their ideas into practice (Staub, 2004). Too often, there is a lack of interaction between designers and teachers. Teachers are expected to autonomously transfer and apply educational systems and results of educational research. This, however, is an extremely complex task and may result in limited or inadequate implementation of the innovative design. Secondly, at the school level teachers work under particular conditions that may hamper the good implementation of an innovative design. For instance, smooth implementation may be hampered by a lack of time, large group sizes, inappropriate textbooks and media, and available classrooms that do not allow for individual work or work in small groups (Roelofs & Terwel, 1999; Verloop & Lowyck, 2003). Third, teachers’ perceptions of student characteristics influence the choice and realisation of a learning environment. For example, if teachers perceive that less able students are overcharged in the learning environment, then they are likely to change or adapt it (Roelofs & Terwel, 1999). Moreover, the perceived lack of passion in today’s students may also negatively affect the implementation of new teaching practices (Simplicio, 2004). Fourth, teachers need to believe that they have the skills for implementing the innovation and thus have a positive expectancy of success with regard to the implementation in the specific context they are working in (Abrami, Poulsen, & Chambers, 2004).

Apart from the aspects that teachers report as obstacles for innovating their educational practices, innovations may also suffer from teachers’ unintended failure to incorporate new ways of teaching. Teachers’ perceptions, desires and dissatisfaction (jointly called the “teacher’s perspective”) do not only reflect limiting preconditions from the outside world but also from the teachers’ realm of thought. In the literature, four possible causes are described for teachers’ resistance to innovations: (1) willingness to learn, (2) lack of consciousness of teaching behaviour, (3) incomplete reflection, and (4) dominant conceptions of teaching and learning.

First, teachers’ willingness to learn is a crucial factor for implementing educational innovations. Teachers can be divided into three groups having different patterns of behaviour indicating their willingness to learn (Van Eekelen, 2005). Teachers who do not see why there is a need to learn hold on to old teaching habits, do not have an open mind for others, are not very critical of their own role in education, and seldom reflect or ask themselves questions. Teachers who wonder how to learn want to improve their teaching practices, but do not know how to accomplish this. They are mostly critical of their own role and are a bit more open to others. Teachers who are eager to learn want to improve their performances and undertake action in order to learn. They are alert to classroom processes, have an open mind for others, and are critical towards their own role.

Second, a lack of consciousness of own teaching behaviour can make traditional teaching practices highly persistent. Only part of teachers’ teaching behaviour is conscious and reflective (Tigchelaar & Korthagen, 2004). Routines and spontaneous, immediate reactions determine much of a teacher’s classroom behaviour. Teachers have to react very quickly to things happening in the classroom when
educating about 25–30 students. Because these unconscious behaviours and routines are based on earlier and often more traditional educational experiences, they may interfere with the implementation of educational innovations that expect new teaching behaviours from teachers.

Third, teachers reflect only on a part of the whole educational process. They mainly reflect on the desired manifestation of their teaching, which means that they focus on the educational methods and strategies they plan to use in their lessons (Ponte, Ax, Beijaard, & Wubbels, 2004). They rarely reflect on the current educational reality and the effects of their teaching behaviours (ibid). This one-sided way of reflecting on education is likely to hamper the implementation of educational innovations.

Finally, teachers differ in their conceptions of teaching and learning. It has been shown that conceptions influence perceptions. Conceptions can be seen as lenses through which people perceive and interpret the world (Pratt, 1992). Conceptions of teaching and learning can be placed on a continuum between a teacher-centred/content-oriented pole and a student-centred/learning-oriented pole (Kember, 1997). Conceptions on the latter side of the continuum are most compatible with educational innovations based on constructivism and ideas behind powerful learning environments. Teachers' conceptions of teaching and learning are influencing teachers' approaches to teaching (Trigwell, Prosser, & Waterhouse, 1999) and their way of acting and reacting in the learning environment (Pratt, 1992). This implies that conceptions may influence the way teachers implement an educational design through their approaches to teaching, which can be seen as an operationalisation of their conceptions. This influence could be reflected in teachers' perceptions of the learning environment, desires, and dissatisfaction with the current learning environment.

Practical experiences at the level of design, school, students, and teachers' own competencies and self-efficacy, as well as teachers' individual characteristics, are reflected in teachers' perceptions of the learning environment, the way they would like the learning environment to be (i.e., desires), and their dissatisfaction with elements of the current learning environment. So, teachers are able to give important feedback to those who designed the educational innovation (see also Könings et al., 2005; West & Staub, 2003). The perspective of teachers provide information about the practical side of the design, which is in fact indispensable for designers.

Only informing designers about teachers' experiences with the designed learning environment, would be the weakest form of cooperation between designers and teachers (i.e., implementors) (Kensing & Blomberg, 1998). A stronger form of cooperation is participatory design, aiming at an active participation of users in the design process and in decisions that will affect them (Kensing & Blomberg, 1998; Markin, 1997). Participatory design is already used in business (Mumford, 1997) and in developing technology (Mankin, Cohen, & Bikson, 1997), and more specific in the design process of computer applications (Bodker, 1996). The participatory design process constitutes analysis of needs and possibilities, generation of visions for change, project management, and planning for implementation (Kensing, Simonsen, & Bodker, 1998). Some important benefits of participatory design are: (1) an improved quality and usability of the design, (2) easier acceptance of innovations by its users, (3) a better understanding of innovations by the users resulting in a more effective implementation, and (4) less investments in innovations that users do not want or cannot use in practice (Damodaran, 1996).

For good functioning of participatory design it is important to be well-informed on teachers' perspective in implementing a new educational design, and how this is related to teachers are individual characteristics. The current study answers the question of how teachers perceive, desire, and appreciate an innovative learning environment, and examines the relation between teachers' perspectives and their approaches to teaching. Additionally, possible relations with the amount of teaching experience, sex, and courses teachers' teaching will be explored. Shortly, the current study answers the following research questions:

1. How do teachers perceive the current innovative learning environment (in Dutch secondary education), what do they desire in a learning environment and with which elements of the perceived learning environment are they dissatisfied?
2. How are perceptions, desires, and dis/satisfaction related to approaches to teaching, amount of teaching experience, sex, and courses teachers are teaching?
1. Method

1.1. Participants

The sample consisted of 142 teachers of five schools for secondary education in the south of the Netherlands. They were all teaching 10th grade students (about 16 years old) in senior general secondary education and/or pre-university education and were expected to implement the innovative learning environment, called “Second Phase”. The teachers’ mean age was 44.40 years (SD = 9.77), having on average 18.40 years (SD = 10.21) of teaching experience. The sample consisted of 47 female teachers (33.8%) and 92 male teachers (66.2%) Three teachers did not indicate their sex. The participants were teaching different kinds of courses (see Table 1). Four teachers did not specify which courses they were teaching.

1.2. Materials

The learning environment: The context of this study is a nation-wide innovation in Dutch secondary education, called “Second Phase” (Ministerie van Onderwijs, Cultuur en Wetenschap, 2005; Stuurgroep Profiel Tweede Fase Voortgezet Onderwijs, 1995; Veugelers et al., 2004). This learning environment requires students to acquire skills and knowledge in an independent way, better preparing them for higher professional education and university. Students learn in a self-directed way with opportunities for collaborative learning. In this learning environment there is more room to account for individual differences than in the traditional class situation. The teacher has to be sensitive to student’s individual progress and problems. The learning process is not only directed to knowledge acquisition, but also to the selection and processing of the vast amounts of information available today. In this learning environment the teacher serves more as a coach and less as an instructor. This creates more possibilities for contact between students and the teacher. Furthermore, learning contents are actualised and broadened. Building a broad general knowledge base is an important educational goal of the Second Phase. The integration of different subject matter domains is emphasised. Courses are clustered in profiles or “themes” of closely interconnected subject matters. According to the educational designers of the learning environment, this enables more integration between subjects and leads to a better preparation for higher professional education and university. In addition to more integration between subjects, the coherence between knowledge and skills is emphasised and the application of acquired knowledge is stressed.

Background questionnaire: This short questionnaire is aimed to get insight into teachers’ individual background characteristics. It contained four open questions about the teacher’s age, the number of years of teaching experience, sex, and the courses taught.

Inventory of Perceived Study Environment Extended-Teacher (IPSEE-T): The aim of the IPSEE-T is to measure teacher’s perceptions of a particular learning environment and their desires with regard to the design of a learning environment. These measures together give insight into teachers’ dis/satisfaction with the learning environment, by looking at the discrepancies between perceptions and desires.

The IPSEE-T consists of 67 items. Thirty-one of these items originate from the inventory of perceived study environment (IPSE; Wierstra, Kanselaar, Van der Linden, & Lodewijks, 1999), translated into Dutch by the Expertise Centre Active Learning of Maastricht University (Picarelli, Bouhuijs, & Vermunt, 2006). To measure the characteristics of powerful learning environments more completely, as described by Könings et al. (2005), another 36 items were constructed. The original version of the IPSE is intended for completion by students. For the current study the IPSEE-T has been adapted for administration to teachers.
The items of the IPSEE-T cover eight scales (see Table 2) that are considered as central characteristics of powerful learning environments. The first scale is fascinating contents and contains items about the extent to which the learning contents are interesting, challenging, and personally relevant for students. The second scale is productive learning. The less the emphasis on sole reproduction of learning contents, the higher the score on this scale. Thus, scores on this scale are reversed in order to express productive learning. The third scale is integration and includes items about the integration of newly acquired knowledge with prior knowledge, the integration of different knowledge domains, and the integration of knowledge and skills. The fourth scale is student autonomy and intends to measure the attention to student’s self-steering with regard to the content of learning, the way of learning, and time planning. The fifth scale is interaction, which incorporates both collaboration with peers and interaction with the teacher. The sixth scale is differentiation, which inquires after opportunities for students to choose and make different tasks, solve problems in different ways, and use different learning materials. The seventh scale is clarity of goals and includes items about the clarity of instructional goals and task demands. The eighth and last scale is personalisation, which inquires after the availability of tailored teacher support.

Each of the items of the IPSEE-T contains a statement about one of the characteristics of a learning environment and two questions, as illustrated in Fig. 1. The questions are rated on a six-point scale, ranging from totally disagree to totally agree. Scores on question A measure the perceptions of the teacher’s learning environment. Scores on question B indicate what the desired learning environment of the teacher would look like. The discrepancy (i.e., absolute difference) between the scores on questions A and B is defined as the measure of dissatisfaction with the particular learning environment. Increasing discrepancies between perceptions and desires indicate increasing dissatisfaction. Small discrepancies between perceptions and desires indicate low dissatisfaction. It should be noted that low dissatisfaction can also be seen as high satisfaction, but only the term dissatisfaction is used to interpret the results in an univocal way.

Internal consistency is computed for all eight scales, separately for the perception items and the desire items (see Table 2). All Cronbach’s alpha coefficients were above .70, except for two coefficients that were between .60 and .70. Thus, the internal consistencies of all scales were acceptable.

Approaches to Teaching Inventory (ATI): The aim of the ATI (Prosser & Trigwell, 1997) is to measure teaching approaches. The questionnaire contains two scales: information-transmission/teacher-focused (ITTF) and conceptual-change/student-focused (CCSF). These scales represent the extreme teaching approaches on a scientifically well-known continuum of approaches between a teacher-centred/content-oriented pole and a student-centred/learning-oriented pole (see Kember, 1997; Prosser & Trigwell, 1993). The ATI has been translated in Dutch and now contains 11 items. The scale ITTF consists of 5 items ($\alpha = .66$) and the scale CCSF consists of 6 items ($\alpha = .72$). All items are rated on a six-point scale, ranging from totally disagree to totally agree.

### 1.3. Procedure

The participants received an invitation to take part in the study accompanied by the questionnaires and a description of the goal of the study. The first page of each questionnaire contained a description of the aim and the contents of the questionnaire and instructions for scoring the items. Participants first had to fill out the background questionnaire, followed by the IPSEE-T, and the ATI. They could fill out the questionnaires at any moment and place they wanted. In total, 142 of the 246 teachers returned the questionnaires (i.e., 57.7%).

### 1.4. Data analysis

For computing mean scores for each scale of the IPSEE-T, maximally 25% of missing values are accepted. So, if at least 75% of the items at scale...
level were filled out, these items were used to compute the mean score. Looking at the mean scores showed that on each scale for at least 85% of the teachers a mean score could be calculated, except for the scale integration (11 items). For this scale a mean score was calculated for only 63% of teachers. The missing-value procedure was adapted for the integration-scale, because it appeared that three items were not applicable to all teachers. These three items referred to integration of theory lessons and practicals. Not all courses included practicals, with the consequence that part of the teachers could not answer these particular items. Therefore, the procedure for this scale was adapted as follows: if 75% of the eight remaining items of the scale were filled out, then the mean of all answered items (including the three particular items) was computed.

One-sample t-tests were used to investigate whether perception scores and desire scores differ from the neutral score of 3.5. Paired-samples t-tests were used in order to test whether discrepancies between perceptions and desires, indicating dissatisfaction, were significant. Multiple regression analyses were used to investigate relations between perceptions on the one hand, and teaching approaches, years of teaching experience, sex, and courses taught on the other hand. In the first step of the regression analysis dummies for the school variable were entered in the regression model to correct for possible school effects. In the second step, independent variables were added using a stepwise forward procedure. The same analyses were used to investigate relations of desires and dissatisfaction with teachers’ individual characteristics. Only independent variables explaining at least 10% of the variance are reported in the text.

2. Results

For answering the first research question teachers’ perception scores will be reported, as well as the desire and the dissatisfaction scores. In relation to the second research question, statistics of the Approaches to Teaching Inventory will be described. Besides, the results of multiple regression analyses will be reported, showing relations (1) between teachers’ perception scores and their individual characteristics, (2) between desire scores and individual characteristics, and (3) between dissatisfaction scores and individual characteristics.

2.1. Perceptions, desires, and dissatisfaction

The eight mean scores of the different scales of the IPSEE-T (see Fig. 2) showed that teachers perceived the learning environment predominantly as a powerful learning environment. One-sample t-tests showed that on six of the eight scales the perception scores were significantly higher than the neutral score of 3.5 ($p < .01$ for all tests). Teachers perceived fascinating contents, emphasis on productive learning, integration in the learning contents, interaction during the learning process, clarity of goals, and personalisation as significantly higher than neutral. On two scales the perception scores were significantly below 3.5 ($p < .01$ for both tests). Teachers perceived differentiation and student autonomy significantly lower than neutral, although they were still scored higher than 3.0 (i.e., above “a bit disagree”).

The desire scores of the IPSEE-T give insight in the ideal learning environment of the teachers. One-sample t-tests showed that on six of the eight scales the desire scores were significantly above 3.5 ($p < .01$ for all tests), which means that teachers clearly desired most of the characteristics of the learning environment, as measured by the IPSEE-T. Only the desires of productive learning and differentiation did not significantly differ from the neutral score.

The discrepancy between perception scores and desire scores is interpreted as a measure of the dissatisfaction with the perceived learning environment.
environment. By looking at the difference between the perception bar and the desire bar in Fig. 1, the dissatisfaction can be deduced. The more both bars differ, the higher the dissatisfaction (e.g., see fascinating contents). The more both bars match, the lower the dissatisfaction (e.g., see differentiation). Although the size of the discrepancies differs among scales, paired t-tests showed that for all scales the perception scores differed significantly from the desire scores (p < .01). For seven of the eight scales the perception scores were lower than the desire scores. Productive learning was the only scale that showed higher perception scores than desire scores (p < .01). Surprisingly, teachers preferred more reproductive learning in the learning environment than they actually experienced.

Because all discrepancies between perceptions and desires were significant, it is valuable to compute our measure of dissatisfaction with the perceived learning environment and to use it in further analyses. The means and standard deviations of the dissatisfaction scores are presented in Table 3, together with the means and standard deviations of the perception scores and the desire scores. It can be seen from Table 3 that teachers were especially dissatisfied with the extent to which the learning contents are fascinating for students, the room for interaction during the lessons, the integration in the learning contents, and the possibility for student autonomy.

2.2. Approaches to teaching

Teachers reported both the ITTF approach (M = 4.22; SD = .70) and the CCSF approach to teaching (M = 3.91; SD = .73). A one-sample t-test on the scores of the ATI showed that on both scales the means were significantly higher than the neutral score of 3.5 (p < .01). A paired t-test showed that the scores on the ITTF scale were significantly higher than the scores on the CCSF scale, t(133) = 3.57, p < .01. So, teachers considered teaching primarily as information transmission in a teacher-focused educational context.

2.3. Perception scores and teachers’ individual characteristics

Table 4 presents the results of the multiple regression analyses of teachers’ individual characteristics
on the perception scores of the scales of the IPSEE-T. The independent variables included in the analyses are: approaches to teaching, sex, years of teaching experience, and courses taught. The results in Table 4 are corrected for possible school effects, by including the variable school in all models. The analyses showed that part of the variance of the perception scores on different scales was explained by the teaching approaches. The more the teachers reported a CCSF approach to teaching, the higher the perception scores of integration. For the scales student autonomy and interaction, the CCSF approach also contributed to high perception scores. The perception scores of differentiation were negatively related to the ITTF approach. The more the teachers reported this teaching approach, the lower their perception scores of differentiation. The perception of clarity of goals was related to the course teachers were teaching: teachers teaching language courses perceived more clarity of goals than others. Sex hardly related to perception scores, and years of teaching experience did not relate to perception scores on any scale.

In short, the regression models reported in Table 4 show that approaches to teaching are often related to perception scores. Teachers reporting a CCSF approach perceive a more powerful learning environment on half of the scales of the IPSEE-T. Teachers reporting an ITTF approach perceive a less powerful learning environment on half of the scales.

2.4. Desire scores and teachers’ individual characteristics

The results of the multiple regression analyses of teachers’ individual characteristics on desire scores of the IPSEE-T (see Table 5) showed that the more the teachers reported a CCSF approach, the higher their desire scores on integration, student autonomy, and interaction. On the scale differentiation the ITTF approach contributed to low desire scores. Overall, the results in Table 5 show that approaches to teaching explain part of the variance of the desire scores on seven of the eight scales. The CCSF approach was related to high desires. The ITTF approach is two times related to low desires and two times to high desires. The courses the teachers were teaching related to their desire scores on three scales. The number of years of teaching experience and sex show no relation with desire scores.

2.5. Dissatisfaction scores and teachers’ individual characteristics

There was only one significant regression weight in all multiple regression analyses of teachers’ individual characteristics on dissatisfaction scores. Teachers teaching creative courses were more dissatisfied about the clarity of goals ($R^2 = .61; \Delta R^2 = .04; B = .33; SE B = .11; \beta = .20$) than teachers teaching other courses. The lack of significant findings in the multiple regression analyses of the dissatisfaction scores indicate that teachers, independent from their individual characteristics, are all equally dissatisfied with the perceived learning environment. There was no influence of teaching approaches on dissatisfaction. There were also no relations between dissatisfaction scores and sex, years of teaching experience, and courses taught.

3. Conclusions and discussion

The current study gives insight into teachers’ perceptions, their desires, and their dissatisfaction.
with the Second Phase in Dutch secondary education, as well as the relation of these variables with teachers’ individual characteristics.

The first research question focused on the teacher’s perspective of the current innovation in Dutch secondary education. The results show that teachers perceive a predominantly powerful learning environment, except for student autonomy and differentiation. It is particularly remarkable that student autonomy is not perceived as pronouncedly present in the learning environment, because this is one of the elementary characteristics of its underlying educational design.

The desires show that teachers positively value almost all measured elements of a powerful learning environment, including student autonomy. Teachers are neutral about the desirability of differentiation and productive learning. In the light of educational trends such as education-on-demand and adaptive teaching it is striking that differentiation is not an important issue for teachers: they do not recognise it in their own environment and they do not value it very highly. This might be explained by the fact that students are already grouped together in two levels (at school level), based on their capacities: senior general secondary education and pre-university education. However, at class level one might still expect that variation between students in capabilities and interests would give further reason for differentiation.

Note: All multiple regression models are corrected for school effects. $R^2$ is the total amount of explained variance of the model, including school effects. $\Delta R^2$ is the change in $R^2$ after adding a particular significant independent variable to the model. If there is no independent variable significantly predicting a dependent variable, only $R^2$ is reported.
Except for productive learning, the results of dissatisfaction scores show that teachers desire a more powerful learning environment than they perceive at the moment. Teachers are especially dissatisfied with the lack of challenging and fascinating contents, the low amount of interaction during the learning process, the inadequate integration of subject matter, and the amount of student autonomy. Teachers are also dissatisfied with respect to productive learning, but the desire scores are lower than the perception score. Apparently, teachers prefer less emphasis on productive learning than they currently experience in the learning environment, formulated otherwise, they prefer more reproduction of knowledge than they perceive. This is clearly not in line with constructivist ideas, which stress the importance of the construction of knowledge by learners themselves (Jonassen, 1991).

The second research question focused on the relations between teachers’ perceptions, desires, and dissatisfaction on the one hand, and their approaches to teaching, amount of teaching experience, sex, and courses taught on the other hand. Results show that teachers’ perceptions are related to their approaches to teaching. Teachers reporting the CCSF approach perceive a more powerful learning environment, while teachers reporting the ITTF approach perceive a less powerful learning environment. Teachers’ perceptions are sometimes related to the courses taught, hardly related to sex, and never related to years of teaching experience.

A possible explanation for the found relation between perceptions and approaches to teaching (i.e., operationalised conceptions) is that the conceptions influenced the perception process. Conceptions operate as lenses through which one looks (Pratt, 1992). Another plausible explanation is that teachers perceive different educational practices. Teachers all have their own way of teaching and usually only perceive their own lessons. Thus, the object of the perception may have differed, which itself was out of the scope of this study. If teachers teach according to their own approach to teaching, they are likely to perceive a learning environment that is in line with their approaches to teaching. However, this means that they have the freedom to do so because the educational design is not highly prescriptive.

Teachers reporting a CCSF approach desire a more powerful learning environment. The direction of the relation between desires and the ITTF approach is equivocal. The stronger the ITTF approach, the lower the desires for productive learning and differentiation, and the higher the desires for clarity of goals and personalisation. Productive learning and differentiation are less desirable elements of the learning environment if the teacher considers information transmission as the goal of education, doing so in a teacher-focused manner. The clarity of goals and personalisation as characteristics of powerful learning environments, however, can also fit well in the more traditional ITTF approach to teaching.

Dissatisfaction is hardly related to teachers’ individual characteristics. There is a single relation with the courses taught, but no relation with sex and years of teaching experience. Dissatisfaction is totally independent from approaches to teaching: teachers with a CCSF approach and an ITTF approach are equally dissatisfied with the learning environment. This is remarkable, because the design characteristics of the Second Phase fit better to the CCSF approach than to the ITTF approach. A likely conclusion is that all teachers can constitute their educational practices according to their own approaches to teaching to the same extent. If this is true, the educational design of the Dutch innovation in secondary education is only implemented as far as it is in agreement with teachers’ approaches to teaching.

Remarkably, there is a lack of a relation between years of teaching experience and the teachers’ perspective. It indicates that teachers who just graduated and enter practice (mostly young teachers) do not perceive a more powerful learning environment, or are more dissatisfied with the perceived learning environment, than more experienced teachers. This means that young teachers are not more inclined to innovate than their experienced colleagues, which could be explained by quick socialisation and adaptation to the current school practices (Pugh & Zhao, 2003).

What causes can be identified for the hampering implementation of the design of the learning environment? The study showed several aspects that are in contrast with the original design. Teachers perceive the current learning environment as a powerful one, with the exception of differentiation and student autonomy. The autonomy of students is not seen as highly desirable and a productive way of learning is even less desired than perceived. Furthermore, teachers seem to design their education according to their own approaches to teaching. What may cause this incomplete
limited prescriptive educational design places few constraints on teaching behaviours, it is easier to stick to existing behaviours than to change the cognitions. The results of the current study may indicate the design of the learning environment is not well-defined enough.

A limitation of the current study is that the relation between conceptions (operationalised as approaches to teaching) and perceptions cannot be separated from the relation between approaches to teaching and the way in which teachers constitute the learning environment. In order to get more grasp on this, one has to focus, additionally, on the “objective” learning environment, for example with video observations in the classroom. This is an important line for future research. Another limitation of the study is that teachers may have answered the questionnaire in a socially desirable manner. However, if this effect played a role at all, it seems to be small, because the responses on the different scales of the IPSEE-T clearly differentiated and many answers were not in agreement with the design of the innovative learning environment or today’s educational insights.

A practical implication of our study is that an innovative educational design should offer teachers much guidance for how to implement it in practice, because our results indicate that teachers otherwise tend to implement the innovation in accordance with their own approaches to teaching—which are not always in line with the intended design. Therefore, the design needs to be explicit about the teaching behaviours expected from the teachers. However, it is highly necessary that such a design is workable and feasible for teachers. Therefore, a second practical implication is that cooperation between educational designers and teachers should be promoted and become common practice. Because teachers experience problems in the feasibility of the design, they themselves adapt the design to a practical form. These feasibility problems provide important feedback for designers and a starting point for cooperating with teachers more closely in order to develop a more workable design. The principles of participatory design can give practical guidance for this cooperation. By more intensive cooperation between designers and teachers, the scope of the innovative design can be enhanced because it makes it easier for teachers to teach according to the design rather than according to their own approaches to teaching. This is especially relevant for reaching “traditional” teachers when implementing innovations.
To conclude, this study showed the importance of exploring the perspective of teachers who are involved in an educational innovation. It showed that the implementation of the innovative learning environment only partly succeeded and that more cooperation between educational designers and teachers is needed to create more congruence between the educational design and the factual learning environment in the classroom. Such a cooperatively developed design will contribute more to promoting good educational practices than a design developed without acknowledgment of the teacher’s perspective. Furthermore, such a design will be more workable for teachers and, eventually, better able to assist teachers in innovating their education. Making the design more specific and concrete could help more traditional teachers to successfully implement an innovation.
