Giving up Crime

The person centered method Giving up Crime (GUC) promotes recovery and desistance from crime in (ex)detainees by capitalizing on personal strengths and stimulating intrinsic goal restructuring. Although GUC is positively evaluated by detainees and prison officers, insight in the mechanisms underlying these appraisals is scant. This study investigates the effects of GUC on detainees’ emotional experience and perceived levels of support in the realm of daily life.

The Experience Sampling Method (a structured diary technique) was used to assess momentary emotional experience (positive affect – PA; negative affect – NA), self-esteem (SE), perceived (social) support (SUPP), and self-efficacy (EFF) in the daily life of 20 male detainees (age = 34.1 ± 8 yrs), assigned to a GUC (n=8) or waiting list control (WLC) group (n=12). All multilevel analyses were a priori corrected for age and number of prior imprisonments.

No difference was revealed in mean levels of PA between the GUC and WLC group. Mean levels of NA, however, were higher in the GUC group (B=1.24, p<.03), likely linked to the process of reflection which is central to the stage of GUC at which the current study intercepted. The GUC group reported higher levels of SUPP (B=1.54, p=.009), and the experience of SUPP moreover, was positively associated with PA (B=.18, p<.001), SE (B=.07, p=.04), and EFF (B=.15, p=.02) in the whole sample.

The current study opens up new avenues for the study of detention experience by showing, for the first time, that the ecologically valid research method ESM can be successfully implemented in a prison context. Further, higher perceived support levels in the GUC group suggest that the GUC program contributes to a supportive rehabilitation climate.
